Fluid Therapy for Wildlife

What is Dehydration? Dehydration is the loss of water and salts essential for normal body function.

Assessing Dehydration: Skin (Turgor) Tent Test

- Definition: The time it takes for skin pulled away from the body to fall back into a normal resting position.
- Where to Pinch
 - Mammals: skin between shoulder blades
 - Birds: skin over the toes or eyelids
 - **Reptiles**: skin tenting is not a reliable test
- Dehydration is present when it takes longer than one second for the skin to return to a normal resting position.

Assessing Dehydration: Capillary Refill Time (CRT)

- Definition: The time it takes for the capillaries to refill after applying enough pressure to blanch the surrounding area.
- Where to Apply Blanching Pressure
 - Mammals: perform on the gums (can be difficult with aggressive patients)
 - **Birds**: use the basilic/ulnar vein (inside of elbow)
 - **Reptiles**: difficult
- A Capillary Refill Time (CRT) of greater than 2 seconds is indicates dehydration greater than 7%.

Assessing Dehydration: Mucous Membranes

- Definition: Visually examining the color and texture of the mucous membranes.
- Where to look
 - Can evaluate oral membranes, eye conjunctiva, vulva or cloaca.
- What is normal
 - Pale pink to pink membrane color, but know your species not all animals have pink membranes.
 - o Glistening and moist.
 - If membranes are pale and tacky or the animal has thick mucous strands in mouth they are dehydrated.

Route	Advantages	Disadvantages
Oral (PO)	Cheap, very effective, most natural. Helps flush the GI system.	Must be conscious, holding head up and swallowing. Risk of aspiration.
Subcutaneous (SC)	Simple, cheap, effective, can give a large bolus to minimize handling.	Minimal absorption if animal is in shock. Must be administered using sterile technique.
Intravenous (IV) Intraosseous (IO)	Delivers fluid directly into blood volume.	Risk of infection. Stress from catheter placement; can fall out. Risk of fluid overload.
Peritoneal (IP)	Can give a large bolus, absorbed slowly over time.	Risk of infection, puncturing an internal organ.

Routes of Administration

Clinical Signs of Dehydration: Birds

Clinical Signs	Percent Dehydration
No obvious signs, but assume all injured or orphaned birds have a fluid	< 5%
deficit.	
Skin may appear tight, especially over the keel. It may also appear dry and	5-10%
wrinkly. The skin forms a temporary tent if pulled up. Eyes look dull and	
eyelids tent. Inside of mouth is tacky, mucous strands.	
Inside of mouth is dry. Extremities are cold. Skin remains tented when pulled	10-15%
up. Heartbeat is rapid. Bird looks ill, listless and depressed.	

Clinical Signs of Dehydration: Mammals

Clinical Signs	Percent Dehydration	
No obvious signs, but assume all injured or orphaned mammals have a fluid	< 5%	
deficit.		
Skin appears tight; forms temporary tent if pulled up. Inside of mouth is dry.	5-7%	
Decreased capillary refill time. Eyes starting to appear dry and sunken. Urine		
is concentrated and decreased volume.		
Pulse is weak and rapid. Eyes are sunken. Extremities are cold. Skin remains	7-10%	
tented when pulled up. Mucous membranes are pale. Life threatening.		

Clinical Signs of Dehydration: Reptiles

Clinical Signs	Percent Dehydration
Increased thirst, slight lethargy, decreased urates.	3%
	=0/
Increased thirst, anorexia and dullness. Dry loose wrinkled skin; slowly	7%
returns to normal when tented. Dull eyes. Dry, often sticky mucous oral	
membranes. Will start to see dysecdysis (abnormal shedding.)	
Dull to comatose. Skin remains tented after pinching. Animal feels light. Dry	10%
mucous membranes. Sunken eyeballs. No urates.	

Normal Laboratory Values

Test	Birds	Mammals	Reptiles
PCV (Packed Cell Volume)	35-55%	35-55%	20-40%
Total Protein	3.5-5.5 g/dl	5.5-7.5 g/dl	3.0-8.0 g/dl

Fluid Calculations

Patient is a 1.2 kg Red-tailed Hawk that is 8% dehydrated and is losing 7 ml of blood per day as a result of an actively bleeding wound.

Step	Formula	Example
	Convert the weight to g	1.2 kg Red-tailed Hawk
Step 1	1 kg = 1000 g	1.2 kgy 1000 g = 1200 g
	1 ID = 454 g	1.2 kg x 1000 g = 1200 g
	BW (g) x (Maintenance Fluids + Fluid	BW (g) x (Maintenance (6%) + Fluid
Step 2	Deficit) =	Deficit (8%)) =
	PW - Rody Weight in g	1200 g y (606 + 806) -
	Maintenance Fluids = 6%	1200 gx (0.04 + 0.00) = 14% = 0.14
	Fluid Deficit = % Dehydration	
		1200 g x (0.14) = 168 ml
Char 2		
Step 3	step two	
		168 ml + 7 ml = 175 ml
	7 ml of daily blood loss	
	Answer from step two + ongoing losses =	
	Calculate fluid capacity.	Body Weight (g) x 5% =
Step 4		Normal crop/stomach capacity
	Normal Crop or Stomach Capacity Rody Weight (g) x 5% =	$1200 g \times 0.05 (5\%) = 60 cc or ml$
	Maximum crop/stomach capacity	$1200g \times 0.03 (3\%) = 00 \text{ CC OF III}$
		Gavage 60 ml per feeding
	Debilitated Crop or Stomach Capacity	
	Body Weight (g) x 2.5% =	
	Total Subcutaneous (SC) Capacity	
	Body Weight (g) x 3% =	
	Maximum SC capacity	
Sten 5	by the total fluid capacity	1/5 ml for 24 nours / 60 ml = 2.9
July 2	by the total null capacity.	Gavage 60 ml of fluids
	Total fluid requirement (ml) / fluid capacity	3 times per 24 hours
	= fluid frequency per 24 hours	

Therapeutic Fluid Types

Oral Rehydration Solutions

- Commercial products for human pediatric use or calf diarrheal treatments.
- Should contain sodium and some glucose to maximize the rate of water absorption.
- Can be given PO only.

Crystalloids

- Can enter cells and all body fluid compartments.
- Stay in the bloodstream for shorter period of time than colloids.
- Used for replacement or maintenance of blood volume.
- **Isotonic Fluids**: Having the same concentration of dissolved particles as normal body fluid.
 - Can be given PO, SQ, IV.
 - o Lactated Ringers Solution, 0.9% Sodium Chloride, Normosol–R, 2.5% Dextrose, Plasma-LTE
- Hypertonic Fluids: Having a higher concentration of dissolved particles than normal body fluid.
 - Can be given PO or IV only.
 - o >5% Dextrose

Colloids

- Large molecular weight substances that are restricted to bloodstream.
- More of this fluid remains in the bloodstream.
- Ideal for animals in shock.
- Must be given IV or IO.
 - o Hetastarch
 - o Oxyglobin
 - o Whole blood or plasma
